# Reconfigurable highly efficient CMOS-based dual input variable output switched capacitor converter for low power applications 

C. Abraham ${ }^{\boxtimes}$, V. Subburaj, D. Jena, P. Perumal, B. R. Jose and J. Mathew

> A reconfigurable switched capacitor converter (SCC) topology with nine/ten CMOS switches and two flying capacitors is presented. It is capable of accepting two input sources simultaneously with an input voltage in the range of $1-2.5 \mathrm{~V}$ and delivers the output for 15 conversion ratios. The proposed SCC can drive a load current ranging from $10 \mu \mathrm{~A}$ to 10 mA at an open loop efficiency of $>90 \%$. One of the important applications of the proposed converter is the utilisation of photovoltaic (PV) or the combination of PV and other direct current sources. The regulation of the output voltage can be achieved either by changing the voltage conversion ratios or using variable switching frequency.

Introduction: Fully integrated portable voltage regulators are gaining popularity in global power supplies, renewable energy conditioning, bio-medical applications and so on, due to their miniaturised form with regulation capabilities to operate using a single integrated circuit [1]. The proposed converter in this Letter is capable of delivering 15 output voltage conversion ratios (VCRs). By reconfiguring the switches and flying capacitor connections, different targeted output voltages are generated to operate with low input/output voltages. The proof of validation has been confirmed by mathematical, simulation and hardware prototype results.

Proposed CMOS-based switched capacitor converter (SCC) architecture: The layout of the proposed SCC is shown in Fig. 1a. It works for 13 VCRs using nine CMOS switches $\mathrm{S}_{\mathrm{b} 1}-\mathrm{S}_{\mathrm{b} 9}$, two flying capacitors ( $C_{\text {fly } 1}$ and $C_{\mathrm{fly} 2}$ ) and one filter capacitor $C_{\text {out }}$. In addition, two more VCRs are discussed in later sections, but using ten switches. For each VCR, a predetermined pulse sequence is generated for controlling the switches as given in Table 1. Two phases ( $\phi_{\mathrm{c}}$ and $\phi_{\mathrm{t}}$ ), with $50 \%$ duty cycle, are used to charge and discharge the capacitors as shown in Fig. 1a. The work presented in [2] has 14 switches, which includes four diodes that can considerably lower the efficiency due to the forward diode voltage drop. Therefore the attempt in this Letter is to generate 15 against 11 VCRs in [2], using only nine/ten CMOS switches and no diodes. This reduces the component count which increases efficiency at the same time requiring less chip space.

Working principle of the converter: From Table 1 for state $6, S_{\mathrm{b} 1}, S_{\mathrm{b} 4}$, $S_{\mathrm{b} 8}$, and $S_{\mathrm{b} 9}$ are connected in phase $1\left(\phi_{\mathrm{c}}\right)$ the charging phase and $S_{\mathrm{b} 2}$, $S_{\mathrm{b} 3}, S_{\mathrm{b} 5}, S_{\mathrm{b} 6}$, and $S_{\mathrm{b} 7}$ are connected in phase $2\left(\phi_{\mathrm{t}}\right)$ the discharging phase. In phase 1 , the flying capacitors ( $C_{\text {fly } 1}$ and $C_{\text {fly } 2}$ ) are connected through the switches in series and share half the input voltage $V_{\text {bat }}$ from the battery. In phase 2 , the flying capacitors $\left(C_{\text {fly } 1}\right.$ and $\left.C_{\text {fly } 2}\right)$ are connected in parallel together with the second source $V_{\mathrm{s}}$ which can be fed from the solar if desired, delivers the load. To model the equivalent resistance $R_{\text {equ }}$ in Fig. $1 b$ which represents the complete model of the SCC to predict the output voltage, the reduced equivalent circuit of the converter for state 6 is developed in Fig. 2. The CMOS switch resistance is taken as $r_{\text {on }}$ and the capacitor equivalent series resistance (ESR) is resr $_{1}$ and resr $_{2}$.

Fig. 2 Equivalent circuit of series-parallel SCC
a $\phi_{\mathrm{c}}$ State
$b \quad \phi_{t}$ State [2]
Theoretical framework: Theoretical analysis is performed on the SCC for the sixth state $\left(V_{\mathrm{s}}+\left(V_{\text {bat }} \times 0.5\right)\right)$ of Table 1 by utilising two different independent sources. The charging and discharging phase paths are shown by the firm and dotted lines in Fig. 1a. A similar analysis can be considered for other VCRs mentioned in Table 1. Evzelman et al. [3] have proposed an average current-based conduction loss model to develop $R_{\text {equ }}$. This analysis is derived from the basic circuit theory concept of approximating the SCC circuit in any operating phase to a first-order RC network. During a time period corresponding to a switching frequency, if charging and discharging processes in $C_{\text {fly } 1}$ and $C_{\text {fly } 2}$ are completed then the transition state is fully charge or slow switching limit and this occurs when the switching frequency is small or time period is large. On the contrary, if the switching frequency is large, then the time period is small the flying capacitors cannot completely charge and is said to be in the zero charge or fast switching limit mode where the current is constant in $C_{\text {fly } 1}$ and $C_{\text {fly } 2}[1,3]$. The average capacitor current in $\phi_{\mathrm{c}}$ and $\phi_{\mathrm{t}}$ is mapped to the $I_{\mathrm{out}}$, given by [2, 3], where $R_{\text {equ }}$ referred in Fig. $1 b$ is the sum of the equivalent resistance defined by both the charge and discharge phases. Fig. 2 shows the equivalent circuit of the SCC

$$
\begin{equation*}
P_{\text {equi }}=I_{\text {out }}^{2} R_{\text {equi }} \tag{1}
\end{equation*}
$$

If $T_{\phi_{\mathrm{c}}}$ and $T_{\phi_{\mathrm{t}}}$ are the time period during the $\phi_{\mathrm{c}}$ and $\phi_{\mathrm{t}}$, then

$$
\begin{gather*}
\lambda_{\phi_{\mathrm{c}}}=\left[\left(T_{\phi_{\mathrm{c}}} /\left(4 s_{\mathrm{b} \phi_{\mathrm{c}}} * r_{d(\mathrm{on})}+2 \operatorname{esr}_{\phi_{\mathrm{c}}}\right)\left(C_{\mathrm{fly}} / 2\right)\right)\right] / 2  \tag{2}\\
\lambda_{\phi_{\mathrm{t}}}=\left[\left(T_{\phi_{\mathrm{t}}} /\left(3 s_{\mathrm{b} \phi_{\mathrm{t}}} \times r_{d(\mathrm{on})}+\operatorname{esr}_{\phi_{\mathrm{t}}} / 2\right)\right.\right. \\
\left.\left.\times\left(2 C_{\mathrm{fly}} \times C_{\mathrm{out}} / 2 C_{\mathrm{fly}}+C_{\mathrm{out}}\right)\right)\right] / 2 \tag{3}
\end{gather*}
$$

During $\phi_{\mathrm{c}}$ and $\phi_{\mathrm{t}}$ to get $R_{\text {equ }}$ the corresponding equivalent resistances are given as

$$
\begin{gather*}
R_{\mathrm{equ} \phi_{\mathrm{c}}}=\frac{0.125 \operatorname{coth} \lambda_{\phi_{\mathrm{c}}}}{f_{\text {switch }} \times 0.5 C_{\text {fly }}},  \tag{4}\\
R_{\text {equ }_{\mathrm{t}}}=\frac{0.5 \operatorname{coth} \lambda_{\phi_{\mathrm{t}}}}{f_{\text {switch }}\left(\left(2 C_{\text {fly }} \times C_{\text {out }}\right) /\left(2 C_{\text {fly }}+C_{\text {out }}\right)\right)} . \tag{5}
\end{gather*}
$$

By combining and approximating (4) and (5), the $R_{\text {equ }}$ of the converter is

$$
\begin{equation*}
R_{\mathrm{equ}}=\frac{1}{4 f_{\text {switch }} \times C_{\text {fly }}}\left[\operatorname{coth}\left(\lambda_{\phi_{\mathrm{c}}}\right)+\operatorname{coth}\left(\lambda_{\phi_{\mathrm{t}}}\right)\right] . \tag{6}
\end{equation*}
$$

Once $R_{\text {equ }}$ is known $V_{\text {out }}$ referred in Fig. $1 b$ can be calculated since $V_{0}$, $I_{\text {out }}$ and $R_{\text {out }}$ are also known. The model derived $R_{\text {equ }}$ and the calculated $V_{\text {out }}$ for different frequencies are shown in Table 2. Both the source voltages are assumed same and are taken as 1.17 and 2 for 100 and 5 kHz , respectively.

Table 2: Modelling, simulation and hardware comparison for sixth state

| $f_{\text {switch }} \mathrm{kHz}$ | $\lambda_{\phi_{\mathrm{c}}}$ | $\lambda_{\phi_{\mathrm{t}}}$ | $R_{\text {equ }}$ | $V_{\text {out }}$ <br> model | $V_{\text {out }}$ <br> simulation | $V_{\text {out }}$ <br> hardware | $\eta$ <br> Hardware |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 100 <br> (source $=1.17 \mathrm{~V})$ | 3.24 | 1.43 | 0.25 | 1.75 | 1.75 | 1.74 | $99 \%$ |
| 5 (source $=1.2 \mathrm{~V}$ ) | 1.62 | 7.17 | 5 | 1.76 | 1.78 | 1.74 | $96.5 \%$ |

Implementation and key results: For validation of the converter, the prototype developed is shown in Fig. 3. The switches $S_{\mathrm{b} 1}-S_{\mathrm{b} 9}$ used are bi-directional SPST analogue switches manufactured by MAXIM INTEGRATED circuits MAX4678 with individual $r_{\text {on }}=0.3 \Omega$. The flying capacitor and filter capacitor are manufactured by SANYOUNG $22 \mu \mathrm{~F}, 50 \mathrm{~V}$ with an ESR of $100 \mathrm{~m} \Omega$. The load current ranges between $10 \mu \mathrm{~A}$ and 10 mA at an output voltage level of $0.55-2.5 \mathrm{~V}$. Fig. $3 a$ shows a prototype of the PIC16F controller which is used to generate a switching sequence for the CMOS switch and liquid-crystal display are used to display the particular state of the proposed converter. The dead time is 10 ns . Fig. $3 B$ shows the MAX4678 SMD bidirectional switch and the prototype size is $5 \mathrm{~cm} \times 5 \mathrm{~cm}$ including all components. Fig. $3 C$ shows the test bench of the proposed prototype where a light emitting diode is used as a load which is highlighted in the circle. The experimental result shown in Fig. $3 D$ corresponds to an input voltage of 1.17 V and the output voltage is 1.76 V which is in good agreement with state 6 . Two frequencies 100 and 5 kHz with a duty cycle of $50 \%$ are implemented and shown in Fig. 4. We can conclude from Fig. 4 that for these frequencies, simulation, modelling and experimental results are in good agreement with each other as shown in Table 2. Fig. 5a shows the comparison of work in [2] with diode and the proposed topology in this Letter without diode. The efficiency increases considerably and is $>90 \%$. The size of the prototype is very much smaller than the size of the existing converter discussed in [2], with two more additional VCRs, is an additional feature of the proposed converter. Fig. $5 b$ shows a comparison of the first 11 VCRs derived by the switching sequence referred in Table 1 for modelling, simulation and hardware results of the proposed circuit. For regulation, the first method is to change the VCRs by proper gating to get the corresponding voltage and the second method is to adopt a variable switching frequency to vary $R_{\text {equ }}$ which in turn gives the desired output variable $V_{\text {out }}$. This can be verified in Table 2 as it is 1.74 for 1.17 V input with frequency 100 kHz against 1.74 for 1.2 V at 5 kHz . Fig. $6 a$ shows the simulation, analysis and experimental results of states 12 and 13 .

Modified circuit of inversion mode: With the addition of one more switch $S_{\mathrm{b} 10}$, in between switches $S_{\mathrm{b} 8}$ and $S_{\mathrm{b} 6}$ of Fig. 1a, two more VCRs in the inversion mode [4] can be realised. The complete results are shown in Fig. $6 b$. The switching states are explained in Table 3 to realise the inversion mode.

Conclusion and future work: A reconfigurable highly efficient CMOS-based dual input variable output buck boost SCC for low-power applications is proposed and verified in this Letter. The converter delivers high efficiency in an open loop with a significant increase in efficiency due to the reduced switch count, low weight and size, making it an excellent choice for on chip integration.
